Listeros,

Flying in the face of recent theories on the peopling of the Americas, a group of geneticists at the University of Michigan working with geneticists worldwide are now positing that the Americas were populated from one group of people in East Asia. They studied 29 Native American groups across North, Central and South America and two Siberian groups.

A unique genetic variant is widespread in populations across the Americas suggesting a single wave of migration or multiple waves from the same place. They say that the genetic variant would not be so widespread if the migration was from different sources. The only other place this genetic variant is found is in Siberia. It also appears that the likely peopling of the Americas by this group is by a coastal route.

They found that populations in Central America and the Andes show genetic similarity.

Science Daily has the story

Any way of stating how all of the previous "wave" explanations are negated by the requirement that a perceived unique genetic variant is all inclusive to the entire pre-Columbian population of the Americas?
