Artificial selection is a special case of natural selection, thus if a limit exists for natural selection, it must apply to artificial selection.

That depends on how you define your terms.

It is conventional to treat sexual selection and artificial selection as /not/ being subsets of natural selection, following Darwin's own usage of these terms.

For purposes of mathematical modeling, artificial selection is undistinguishable from non-artificial natural selection.

I'm not sure about sexual selection since it's probably frequency dependent.
