Without pretending a full categorization of drugs, another group would be composed of those drugs that make people active. Cocaine, metamphetamines, steroids and other psychoactives. These group of drugs is perhaps the most dangerous, both by their known effects on the individual's body as by their impact on the metabolism. This is also a group of drugs that can have real externalities in their consume (effects on other people's well being caused by the fact of their use, mostly negative). They are known to make individuals aggressive and intolerant and instead of having a refractory period have instead an effect of increased tolerance, that makes for an increasing consumption even if they don't create compulsion (compulsion in this case may be a aprt of the increased tolerance). They also have an obvious depressive effect on the individual; the fact that the metabolism is accelerated means that sooner or later the body will need "recharging". This group of drugs doesn't need "side effects", as their very effect is almost certain to propduce permanent effects in an individual's life. It is well known the fact of nose bleeding and heart attacks in users...
