i am also working with some leds (lumileds superflux). My project is to control a circuit of leds that will be a parking light/turn signal. The light while illuminated as parking light mode is set at one brightness, and gets almost twice as bright when turn signal is on. The only diagram i can find for this particular circuit is this <http://www.hidplanet.com/dmiller/PWM.jpg> but being a beginner, im not sure how to construct this complicated of a circuit. i know i should use pc board (or so ive been told) but it is still pretty intimidating. Also, anyone know where i can get a 15v zener diode??

.
