Having a separate switch is not ideal since in this case.

Any ideas anyone?

Could you just diode OR the switch to both contacts?

But he wants to activated two different things, but in the same mechanical space.

Like he said, press the button a tiny bit, and it adjusts the autofocus (and activates the LCD panel if it had gone to sleep). Press the button a bit harder, and the camera actually takes a picture.

One button switch connected to two functions wont' allow you to do the actions independently.

Michael
