You may be able to find a transfer switch that will detect the power loss and transfer to an alternate source in a short enough period of time to keep your computer (or other loads) alive. The impression I have recieved is that computer power supplies have changed over the years, lengthening the time period that they withstand a power loss condition. The reason behind these changes, being to reduce the complexity and hence cost of the upstream transfer switches.

I would suggest starting your search at the Asco website. I believe that they make relatively inexpensive devices, though the term inexpensive may be subjective..

.
