I'm aware of opamp theory and I understand why some engineers think there's no reason to "sonically evaluate" opamps. However, I have my reasons for doing so and if anyone thinks me a fool for doing so, so be it. They ain't got'ta be so arrogant and snobbish about it however.

(Just a fool that gets results)

Not a fool, just a bit naive. You are giving little credit to other qualified people who have actually looked at these issues in depth. You are making the assumption that *they* are the fools. For example, some actually have extensive professional experience in analogue design and pro audio, from both a technical point of view and as a musician. Some of these, after such extensive study, indeed conclude that there is no reason to listen to an amplifier in order to design a straight piece of wire with gain. Its purely a technical issue based on gains, distortion, bandwidth, noise etc. Sure to design a tube distortion circuit does require listening to it, but thats irrelevant to the design of the actual amplifier circuits.
