Hi Mike
Thanks for the reply

Have you tried basic troubleshooting like removing all the drives and cards and reseating the memory then powering it up? If that doesn't work, remove everything except the processor and power it up. It should give you some beep codes (memory or video) if the board and processor are working.

– Mike

Yup – tried all that.... no change to the reported symptoms.

I've just ordered a 'drop in' motherboard bundle – let's hope that fixes it (after all – there's not much else to go wrong !)

I had a dead computer donated recently that had a bad momentary switch. Gateway had used some strange type of black glue to hold it to the front of the cabinet, and it had softened up to the point it would slide back in its mount instead of letting the plunger move. A quick cleaning and some decent glue, and it works OK.
