I have a lcd monitor with bad internal power supply. The power supply is responsible for 12V to the video board. And then the video board gives 12V to the inveter.

The voltage on the power board is not very stable, it jumps around 11.56– 12.45V and causes the LCD to shut down and restart every 0.5 second.

Question: Can i use a computer PC ATX power supply 12V to power the video board and turn on the LCD and verify the condition of video board ?

Thanks!

Sure, but that voltage range you're seeing shouldn't be a problem. Sounds like there's another fault in the monitor causing the load to fluctuate.
