I have red coming though when there shouldn't be anyone on the screen.
For instance, If I am at a no-input screen I can see some red on the screen.

There are typically separate red/green/blue level and drive adjustments in a TV set; get a good grayscale test pattern (I assume you can hook up a DVD and load a test disk) and adjust levels until the black band is without tint, then adjust the level controls until the white band is also neutral (white) in color.

These adjustments are on/near the video amplifier board, and always well labeled (like, with red/green/blue colored knobs). The SCREEN control also may be beneficial, it's likely to drift with time. I'm not sure if you have a one-CRT or three-CRT or LCD or DLP type projector, though...

Projection TVs also will benefit from dusting of the optics.
