Below is a thought that may be actually possible in my mind of course.

(thinking is better than not thinking)

Maybe some people that know more about what I state can improve the entire thing.

I typed this kinda fast so please feel free to ask questions if you do not understand any part of it.

I hope some of you will understand the idea and give it thought and of course I hope someone has the time and money to test it (maybe in a small prototype) and maybe even become rich off it is it is able to work like I think it will.

I ask only 2 things if it does get built and works like I think it would.

- 1:) I get my name in part of the invention.
- 2:) If you get rich, I would like a nice compensation for handing it out for free.

Insults and such will be ignored.

Here goes...

The water-gravity transference energy production machine.
by James M Driscoll Jr (aka Spaceman)

The idea is to have 2 containers and enough water to fill one to the top.

2 power generators, and piping and valving and water pumps wherever needed.

Also 2 heavy masses that will float.

and some sort of controller unit for all of it.

and Storage batteries to start it all up and store any energy created.

(and of course a Grid Tie system if it actually works)

Here is the thought on how it would work.

Possible energy invention by James M Driscoll aka Spaceman?

The masses are connected to gear rods
(like a rack and pinion rack) that will turn
an electric generators gearing system on the way
up and also can do such on the way down in each tank
We will start with an empty container A and the floatable mass at
the bottom and a full container B with the floatable mass at the
top.

A pump will start a siphon from B to A that will do just about
half the filling from container B to container A and lift the floatable
mass and the gear rod will be connected that will turn a generator's
gearing to create power from Generator A on the way up and generator B
on the way down and the rest of the way a water pump will complete the
transfer.

The mass must be heavy enough to turn the generator via gravity
when the water is lowering and the gear ratio to turn the generators
would need to be pretty large. (I figure water can pick up lots of weight)
so a large mass would be better for the downward travel to make sure
the high gear ratio will still spin.

that is basically it...

and of course...

Once finished transferring water from A to B, basically the opposite will
happen.

causing the floatable masses to now move downward and upward again creating
electricity again.

Now, who wants to make this thing and become rich selling power
to the World without burning any gas.

:)

Pumps could run off solar or wind to "jumpstart" the system.

Also instead of a syphon in between there could ge a pipe with a water
propelled generator that would also gather energy til about half
of the fill.

Hope someone can understand how I see it all working.

Good luck,

I wish I had a few bucks to test it, but alas I do not.

James M Driscoll Jr
