The 'mean sun' is indeed a fiction. That was known, and the fact duly used, since its inception. But it is a useful thing to declare a day to be 24 hours, as measured by stable chronometers, rather than to rely on solar observations of meridian crossings and then be recomputing the length of the second every day, or changing how many seconds there are in the day, every day.

We also have, in science, the equally fictitious idea of 'standard temperature and pressure'. It's useful to define, but outside of certain contrived situations, never actually occurs. Does that bother you too?

>to the next.*

Actually, no, you don't. First, and probably major for your misunderstandings, is that the Maya (and others) did not determine the year as being 365 days, 5 hours, 49 minutes. To make that determination, one needs a chronometer that measures hours and minutes (and which uses 24 hours in a day, which the Maya did not, and 49 minutes in an hour, which is unlikely -- minutes per hour is legacy of sexigesimal arithmetic, for which Babylon was the only source. The Maya used 10 or 20 for math.)

What they actually determined was the length of year being 365.242+ days. Closer to how they'd have done it, they determined the year to be $365 + 1/4 - 1/128$ days. One route to the determination is to measure the elevation from the horizon of bright stars at sun rise and sun set. They move approximately 1 degree per day. Repeat for 366 days, and you'll find that on the 365th day, the star was 1/4th degree shy of getting back to where it was when you started, but on day 366, it is 3/4th of a degree past the point. Repeat over 32 years (Mayan records, as do many others, extend for more than a century), and you've got another 1/4th degree discrepancy.

At no time does anybody need a chronometer, nor high precision measuring equipment. 1/4th degree is half the width of a full moon, i.e., very large optically.

To the extent the sun is involved in the measurements, it is the actual, observed, sun. So you're happy, right?

You really should read the page you link to. It is a nice description of what was done and how. Flamsteed was testing (asking Towneley to test) the constancy of the period of the

earth's rotation (as referenced to the fixed stars). After the year-long trial, the observations demonstrated that the earth's rotation period was indeed constant.

Having *_tested_* that the earth's period of rotation is constant — is *_this_* the part you object to? That the rotation period is constant? Or are you objecting to the notion that the earth rotates?

So, they *_tested_* that the earth's period of rotation is constant.

Given that observation, one then needs to explain why it is that the sun's motion through the sky is *_not_* constant, as measured by fixed, reliable chronometers (clock or rotation of the earth referenced to the stars).

Is it instead your complaint that the sun really does move through the sky at 24 hours per day, exactly, and it is the rotation of the earth, motion of stars, periods of pendulums, vibration of cesium atoms, ... that are all varying in agreement with each other, but not with your declaration that the actual sun takes exactly 24 hours to return to the meridian?

Notwithstanding your declarations, there's nothing geocentric about anything I've said. We have observations taken from the earth. One must explain those observations. It doesn't matter whether you center yourself at the sun, the core of the Milky Way galaxy, or M87. You still have to explain why observers standing on the earth see what they see.

>> *This fact seems to be causing you some angst?*
>>
>> *The motion of the fixed stars (the 23:56:04), however, is a different matter. That motion shows outstanding constancy.*
>> *It's an easy observation, but the constancy is so great that you need an excellent time piece. Just look for a star crossing your meridian and time how long it is until it is back in the same position. The time for this varies by no more than a few thousandths of a second.*

The picture you reference is a pretty one, and a common one.
Has nothing to do with the structure of the universe, but does
illustrate the apparent motion of the stars, and is entirely
in keeping with the earth rotating.

But what's your objection to 'every point is the valid center' of the
universe? I'd describe it as '_a_ valid center', but that's details.
You're ticked off somehow about geocentrism, which is fine. But
if it's not to be geocentric, and it's not to be relativistic, then
what _is_ your preferred center to the universe? And how did you
decide that?
