My daughter found the pebble shown at:

<http://www.JustPhotos.ca/misc/images/pebble.jpg>

It was lying on the ground near Dryden, Ontario, Canada (N49.807°, W92.856°). Can anyone tell us about the nature of this pebble that has a light coloured core, inside the harder, darker shell? There was nothing similar to be seen in the area but I guess we wouldn't have noticed this one either if it had not been already split in two. Thanks for any comments offered.

As Carsten says, Limonitic concretion is a good guess.
