Hello world,

I am currently working with 128*128 big color images of objects taken in front of a black background. Now I would like to segment the image (to deal only with the object and discard the background) and would like to extract the area and perimeter of the object as well. (eventually medial axis transform).

Are there any open source C/C++ libraries which can do these basic things? I read about one here in the google groups but this is not available anymore (imagelib.rhk.dk)..

I heard of openCV from intel.. is this capable of doing these things?

Thanks in advance for your help,
greetings
Tim
