Hi all,

I'm trying to prove that, if  $\mu$  is a semifinite measure on a sigma-algebra and  $E$  is a measurable set such that  $\mu(E) = \infty$ , then, for every  $\epsilon > 0$ , there's a subset  $F$  of  $E$  with  $\epsilon < \mu(F) < \infty$ .

First, I noticed that, if  $\mu(F) = \epsilon < \infty$  for some subset  $F$  of  $E$ , then the additivity of the measure implies that  $\mu(E \setminus F) = \mu(E) - \mu(F) = \infty - \epsilon = \infty$ . Since  $\mu$  is semifinite, it follows  $E \setminus F$  contains a subset  $G$  with  $0 < \mu(G) < \infty$ . And since  $F$  and  $G$  are disjoint subsets of  $E$ ,  $H = F \cup G$  is a subset of  $E$  such that  $\mu(H) = \mu(F) + \mu(G) > \mu(F) < \infty$ . This shows for every measurable subset  $F$  of  $E$  with finite measure there's a measurable subset  $H$  such that  $\mu(F) < \mu(H) < \infty$ . But this doesn't show the desired proposition.

If, by way of contradiction, we assume there's a  $\epsilon > 0$  such that  $\mu(F) \leq \epsilon$  for every subset  $F$  of  $E$  with finite measure, then there exists  $s = \sup\{\mu(F) \mid F \text{ is a subset of } E \text{ with finite measure}\}$ . In virtue of the first conclusion, this implies  $s$  is not in  $S$ . But this doesn't lead to a contradiction, we don't conclude  $S = \infty$ .

Could anyone give a hint, please? Maybe we could construct an ascending sequence of sets  $F_1 \subset F_2 \subset \dots \subset F_{n+1} \subset \dots$  whose union is  $E$  and such that  $\mu(F_{n+1}) - \mu(F_n) \geq k$  for some  $k > 0$ .

Artur
