what's that "law" about the occurrence of more 1s than 9s (and so on)  
in tables of logarithms e.g.?

fractions & powers of pi, gamma of pi etc. must also have this  
"normal" property;

Yeah -- if I'm thinking of the same thing -- what \*is\* that theory  
about tables of "random" numbers generated from apparently adequate  
pseudo-random sources actually being systematically biased towards  
certain numbers? I remember reading about it once and, as I recall,  
failing to understand it. Is it something to do with the first digits  
of numbers? That rings a faint bell.

No joy with Google ... could anyone explain or give a reference?
