To do so,  
however, I  
believe I  
need to  
understand  
the solution  
to a  
subproblem:  
finding  
 $\tau_k(n) =$   
 $|\{ d : d | n,$   
 $\Omega(d)$   
 $= k \}|.$   
That  
is to say, the  
number of  
divisors of  $n$   
that have  
precisely  $k$

Re: counting divisors/submultisets

(not necessarily distinct) prime factors. This is equivalent to finding the number of  $k$ -element submultisets of a multiset that has multiplicities corresponding to the prime powers in  $n$ .

I'd think of it this way:

given nonnegative integers  $n_1, \dots, n_m$  (the multiplicities) you want to count the number of  $m$ -tuples  $(x_1, \dots, x_m)$  such that  $0 \leq x_i \leq n_i$  for all  $i$ , and  $\sum_i x_i = k$ .

This is the coefficient of  $t^k$  in  $G(t) = \prod_{i=1}^m (1 + t + \dots + t^{n_i}) = (1-t)^{-m} \prod_{i=1}^m (1-t^{1+n_i})$ .

Another way to get it is with recursion: you want  $F_m(n_1, \dots, n_m; k)$  where  $F_1(n_1; j) = 1$  for  $0 \leq j \leq n_1$ , 0 otherwise,

and

$$F_{m+1}(n_1, \dots, n_{m+1}; j) = \sum_{i=\max(0, j-n_1-\dots-n_m)}^{\min(j, n_{m+1})} F_m(n_1, \dots, n_m; j-i)$$

## Re: counting divisors/submultisets

Thanks Robert – when you put it like that it doesn't look so promising.

I also considered constructing them in another way, with another auxiliary function: given  $n = \prod\{p_i^{a_i}\}$ , let  $g_k = |\{i : a_i \geq k\}|$ . Then we get:  
 $\tau_1(n) = g_1$   
 $\tau_2(n) = C(g_1, 2) + g_2$   
 $\tau_3(n) = C(g_1, 3) + g_2(g_1 - 1) + g_3$   
etc. But that's essentially iterating over partitions, and doesn't offer me any additional hope for a closed form or fast calculation.

However I have observed (and do not know how to prove) that it seems:  
 $\sum\{k \equiv 0 \pmod{2}\} \tau_k(n) = \text{ceil}(\tau(n)/2)$   
 $\sum\{k \equiv 1 \pmod{2}\} \tau_k(n) = \text{floor}(\tau(n)/2)$   
and this was one of the things that gave me hope further regularity could be found, and perhaps that prior study of  $\sum C(n,k)$  over arithmetic progressions of  $k$  would provide hints as to where to look for more.

Hugo

Well, this should be one of the things the generating function is good for. If  $\tau_k(n)$  is the coefficient of  $t^k$  in  $G(t)$ , the sum of  $\tau_k(n)$  for even  $k$  is  $(G(1) + G(-1))/2$ . Now, as I said,  
 $G(t) = \prod_{i=1}^m (1 + t + \dots + t^{n_i})$   
so  $G(1) = \prod_i (n_i + 1) = \tau(n)$ .  
If any  $n_i$  is odd,  $G(-1) = 0$ ,

Re: counting divisors/submultisets

making  $(G(1) + G(-1))/2 = \tau(n)/2$ .

If all  $n_i$  are even,  $\tau(n)$  is odd and  $G(-1) = 1$ , so

$(G(1)+G(-1))/2 = (\tau(n)+1)/2 = \text{ceil}(\tau(n)/2)$ .

More generally, I guess you could look at the sum of  $\tau_k(n)$  for  $k$  in a congruence class mod  $p$ , and relate this to the values of  $G$  at the  $p$ 'th roots of unity.

Ah, gotcha, it hadn't occurred to me you could do things like that with the generating function. I had better go read up on them a bit.

For mod 3, and with  $n = \prod_{i=1..m} \{p_i^{a_i}\}$  I then get:

Let  $k = \sum \{ c(a_i \equiv 1 \pmod{3}) \}$

$G_3 = G(1) + G(1^{1/3}) + G(1^{2/3}) = \tau(n) +$   
 $\{ 0 \text{ (exists } i: a_i \equiv 2 \pmod{3}) \}$   
 $\{ 2 \text{ (} k \equiv 0 \pmod{6} \text{)} \}$   
 $\{ 1 \text{ (} k \equiv 1 \pmod{6} \text{ or } k \equiv 5 \pmod{6} \text{)} \}$   
 $\{ -1 \text{ (} k \equiv 2 \pmod{6} \text{ or } k \equiv 4 \pmod{6} \text{)} \}$   
 $\{ -2 \text{ (} k \equiv 3 \pmod{6} \text{)} \}$

.. which nicely generates the count of divisors with  $0 \pmod{3}$  factors as  $G_3/3$ . I don't immediately see how to extend that to yield a count for  $1$  or  $2 \pmod{3}$ , but I'll go away and try a few things out.

Thanks very much,

Re: counting divisors/submultisets

Hugo

Let  $w$  be a primitive cube root of 1.

If  $w$  is a primitive cube root of 1, I get  $G(w) = 0$  if some  $a_i \equiv -1 \pmod 3$ , otherwise  $(1+w)^K = (-1/w)^K$  where  $K$  is the number of  $a_i \equiv 1 \pmod 3$ .

The sum of  $\tau_k(n)$  for  $k \equiv 1 \pmod 3$  is  $(G(1) + 1/w G(w) + w G(1/w))/3$ .

The sum of  $\tau_k(n)$  for  $k \equiv 2 \pmod 3$  is  $(G(1) + w G(w) + 1/w G(1/w))/3$ .

If some  $a_i \equiv -1 \pmod 3$  we have  $G(w) = G(1/w) = 0$  so the counts for  $k \equiv 0, 1$  and  $2 \pmod 3$  are all  $\tau(n)/3$ .

Otherwise, let  $K$  be the number of  $a_i \equiv 1 \pmod 3$ . Then I get  $G(w) = (-1/w)^K$  and  $G(1/w) = (-w)^K$ , so the counts should be  $(\tau(n) + a(k,K))/3$ , where  $a(k,K)$  is given by the following table, the columns being labelled by  $K \pmod 6$  and the rows by  $k \pmod 3$ :

0	1	2	3	4	5		
0		2	1	-1	-2	-1	1
1		-1	1	2	1	-1	-2
2		-1	-2	-1	1	2	1

I conjecture that this generalizes as:

$$\sum_{k=0}^{\tau(n)} \tau_k(n) \text{ for } k \equiv v \pmod m$$

$$= 1/m \sum_{k=1}^m \{w_m^{-kv} G(w_m^k)\}$$

where  $w_m$  is any (fixed) primitive  $m$ 'th root of 1.

I won't have time to work further on this for a couple of days, but I'll try to pick it up again at the weekend.

Well, maybe I just won't be able to leave it alone. :)

Hugo
