

should I worry about hepatitis c?

should I worry about hepatitis c?

About 2 weeks ago, during a night-time shift, I was suturing up a deep wound on a patient. The patient was a male, and a chronic IV drug user. He was Hep C – positive, had liver enzymes drastically higher than normal, and had just started taking the meds for hep C treatment.

His wound at the time was bleeding heavily.

When suturing, I passed the suturing needle from one side of the wound to another with my fingers. I do remember having grabbed the sharp end of the needle in the middle of suturing and then stuck it into the other side of the wound. (all using my fingers instead of a hemostat)

I wasn't injured (at least not to my knowledge; maybe I was stuck "microscopically" ?) in the process. I didn't bleed and gloves were not visibly punctured, although I remember grabbing the suturing needle by its sharp tips. It was a pretty stupid thing to do.

Is this an occupational exposure? Should I worry about having contracted Hep C ?

.
