As usual, MattLB's response demonstrates a severe reading comprehension disorder. I have been arguing for years that such experiments need to control for the susceptibility of the double bonds to lipid peroxidation. In this case, there is no question that there were many more double bonds in the HSO because they actually determined the amount of omega 6s/3s as well as MUFAs in it. It is in Table 2 of the full study. At least this makes it clear how deluded or deranged MattLB's mind is, if nothing else.

.
