I've been taking an antidepressant, Moclobemide, for over a year. My partner began taking Prozac a month and a half ago.

Today I swallowed a reasonably large amount of his ejaculatory fluid. Within 10 or 20 mins I began to feel ill – dizzy, faint and nauseous. This has never happened after swallowing his semen in the past. Three hours later I was feeling mostly better, just a bit nauseous and weak.

I know that Moclobemide and SSRIs can interact when taken orally. I know it's a long shot, but is it possible that I ingested an amount of my partner's Prozac (or its metabolites)? Has any research been done on the excretion of SSRIs in semen?
