tj Frazir,

I'm not exactly convinced the moon is quite as humanly perceived as for being all that bright bluish as you've suggested.

There are actually better examples (some of which so happen to include the orb of Earth) but, please take notice of the available color images as those obtained from orbit (roughly 100+km above the moon) as depicting a somewhat golden dark amount of a brownish or reddish iron and titanium tint as to the otherwise expected 11~12% average (dark basalt to nearly coal like) albedo hew of what the natural lunar surface color has to offer, as having been viewed under the same raw solar influx as illuminating mother Earth. Notice that it's reflecting as quite a dark substance that otherwise matches the mostly B&W images of corrected color density as having been provided by team KECK or Hubble, and by those of most any other satellite obtained images of corrected color that followed the Apollo sting/ruse of the century.

BTW; none of these following archives proves diddly squat that our TBI proof crews ever so much as orbited the moon in person.

Look--see especially of those frames including the Apollo CM and of it's reentry module as for such offering a perfectly good color and intensity balance or spectrum reference that's pretty damn hard to ignore.

<http://www.lpi.usra.edu/resources/apollo/catalog/70mm/magazine/?14>

Of what else our spooks could have managed were the "Chapel Bell" sorts of S-Band-->Microwave transponder deployment(s) as placed into the EM-L2/ME-L1 sweet spot of the mutual though somewhat interactive gravity-well/nullification zone, thereby establishing the necessary signal point-source of origination and thereby more than contributing ample delay considering that some if not most of the data originated from Earth or at least near Earth to start with.

~
