The second law of Kepler "each planet revolves around the sun in a way that the line connecting planet with sun, will make equal areas within equal times"; In another words, when there is an elliptical orbit around a core and the core is located on one of the focus of the ellipse (the first law of Kepler), the speed of the mass moving along the orbit is: " the closer the mass gets to the core, the faster it moves and the farther it gets from the core, the slower it moves along the orbit ".

I have already explained this event physically using my hypothesis.
