The Europeans have the same technical problems as US, total reliance on hydrocarbon combustion and nuclear energy, the resulting global pollution and greenhouse problems, nuclear proliferation and international strife, and great big SRBs on a perfectly good launcher core, with no manned capsule, and finally, an ISS that is not self sufficient, and has no hydroponic plant growing modules.

Once the Europeans too acknowledge these problems, they too can begin to work cooperatively towards the solutions, and those solutions involve massive international research efforts in cryogenic space flight and hydrogen oxygen electrocatalysis.

It's the corruption and fraudulence thing again, it always comes with the oil and the nuclear power, inevitably resulting in a civilization that is not truly space faring and solar powered, and thus not sustainable.
