Hi,

I am looking for a means to determine how two fits are significantly different from each other.

I have data and made two fits to my data using different fitting functions. The question I have is how to determine whether one fit is significantly better than the other one.

I thought about comparing their Chi square values. This way, I could say that which one is a better fit, but I could not say how much better (significance) it is compare to the other one.

Can anyone help me with this problem?

Thanks in advance.

Young-Jin
