I wish to purchase and install a reticle in one of my Labophot scopes. But when I examine the 10x20 CFN oculars, I see no particular spot for a reticle... all I see, as I look at the underside of the ocular, is approx 1cm of small concentric ridges (looks like threads but they're not continuous.. they're individual ridges and then approx another cm of smooth barrel adjacent to the lens. The ridged portion has a slightly smaller diameter than the smooth portion. If the reticle installs at the interface of ridged and smooth... it seems that it would be unable to reach that spot. (Hope that made sense)

So where does a reticle go and how do I secure it? I figured the location of the reticle would be intuitive... it certainly was on an AO scope I used to use.

Thanks in advance for any advice.

Alternatively, Mr Cunningham could just bring one and install it the next time he's near Chattanooga. My scopes could definitely use servicing. Call me if your available, Kevin.
